

Learn Complete Python In Simple Way

MODULES

STUDY MATERIAL

- A group of functions, variables and classes saved to a file, which is nothing but module.
- Every Python file (.py) acts as a module.

durgamath.py

```
1) x = 888
2)
3) def add(a,b):
4)     print("The Sum:",a+b)
5)
6) def product(a,b):
7)     print("The Product:",a*b)
```

- durgamath module contains one variable and 2 functions.
- If we want to use members of module in our program then we should import that module.
import modulename
- We can access members by using module name.
modulename.variable
modulename.function()

test.py:

```
1) import durgamath
2) print(durgamath.x)
3) durgamath.add(10,20)
4) durgamath.product(10,20)
```

Output

888
The Sum: 30
The Product: 200

Note: Whenever we are using a module in our program, for that module compiled file will be generated and stored in the hard disk permanently.

Renaming a Module at the time of import (Module Aliasing):

- Eg: `import durgamath as m`
- Here durgamath is original module name and m is alias name.
- We can access members by using alias name m

test.py:

```
1) import durgamath as m
2) print(m.x)
3) m.add(10,20)
4) m.product(10,20)
```

from ... import:

We can import particular members of module by using from ... import .
The main advantage of this is we can access members directly without using module name.

```
1) from durgamath import x,add
2) print(x)
3) add(10,20)
4) product(10,20) → NameError: name 'product' is not defined
```

We can import all members of a module as follows `from durgamath import *`

test.py:

```
1) from durgamath import *
2) print(x)
3) add(10,20)
4) product(10,20)
```

Various Possibilities of import:

- 1) `import modulename`
- 2) `import module1,module2,module3`
- 3) `import module1 as m`
- 4) `import module1 as m1,module2 as m2,module3`
- 5) `from module import member`
- 6) `from module import member1,member2,member3`
- 7) `from module import member1 as x`
- 8) `from module import *`

Member Aliasing:

```
1) from durgamath import x as y, add as sum
2) print(y)
3) sum(10, 20)
```

Once we defined as alias name, we should use alias name only and we should not use original name

```
1) from durgamath import x as y
2) print(x) → NameError: name 'x' is not defined
```

Reloading a Module:

By default module will be loaded only once even though we are importing multiple multiple times.

module1.py:

```
print("This is from module1")
```

test.py

```
1) import module1
2) import module1
3) import module1
4) import module1
5) print("This is test module")
```

Output

This is from module1

This is test module

- In the above program test module will be loaded only once even though we are importing multiple times.
- The problem in this approach is after loading a module if it is updated outside then updated version of module1 is not available to our program.
- We can solve this problem by reloading module explicitly based on our requirement.
- We can reload by using reload() function of imp module.

```
1) import imp
2) imp.reload(module1)
```

test.py:

```
1) import module1
2) import module1
3) from imp import reload
4) reload(module1)
5) reload(module1)
6) reload(module1)
7) print("This is test module")
```

In the above program module1 will be loaded 4 times in that 1 time by default and 3 times explicitly. In this case output is

```
1) This is from module1
2) This is from module1
3) This is from module1
4) This is from module1
5) This is test module
```

The main advantage of explicit module reloading is we can ensure that updated version is always available to our program.

Finding Members of Module by using dir() Function:

Python provides inbuilt function dir() to list out all members of current module or a specified module.

dir() → To list out all members of current module

dir(moduleName) → To list out all members of specified module

Eg 1: test.py

```
1) x=10
2) y=20
3) def f1():
4)     print("Hello")
5) print(dir()) # To print all members of current module
```

Output

```
['__annotations__', '__builtins__', '__cached__', '__doc__', '__file__', '__loader__', '__name__', '__package__', '__spec__', 'f1', 'x', 'y']
```

Eg 2: To display members of particular module

durgamath.py:

```
1) x=888
2)
3) def add(a,b):
4)     print("The Sum:",a+b)
5)
6) def product(a,b):
7)     print("The Product:",a*b)
```

test.py:

```
1) import durgamath
2) print(dir(durgamath))
```

Output

```
['__builtins__', '__cached__', '__doc__', '__file__', '__loader__', '__name__',
 '__package__', '__spec__', 'add', 'product', 'x']
```

Note: For every module at the time of execution Python interpreter will add some special properties automatically for internal use.

Eg: `__builtins__`, `__cached__`, `'__doc__'`, `__file__`, `__loader__`, `__name__`, `__package__`, `__spec__`

Based on our requirement we can access these properties also in our program.

Eg: test.py

```
1) print(__builtins__ )
2) print(__cached__ )
3) print(__doc__)
4) print(__file__)
5) print(__loader__)
6) print(__name__)
7) print(__package__)
8) print(__spec__)
```

Output

```
<module 'builtins' (built-in)>
None
```

None

test.py

- 1) <_frozen_importlib_external.SourceFileLoader object at 0x00572170>
- 2) __main__
- 3) None
- 4) None

The Special Variable `__name__`:

- For every Python program, a special variable `__name__` will be added internally.
- This variable stores information regarding whether the program is executed as an individual program or as a module.
- If the program executed as an individual program then the value of this variable is `__main__`
- If the program executed as a module from some other program then the value of this variable is the name of module where it is defined.
- Hence by using this `__name__` variable we can identify whether the program executed directly or as a module.

Demo program:

module1.py:

```
1) def f1():
2)     if __name__ == '__main__':
3)         print("The code executed as a program")
4)     else:
5)         print("The code executed as a module from some other program")
6) f1()
```

test.py:

```
1) import module1
2) module1.f1()
```

D:\Python_classes>py module1.py
The code executed as a program

D:\Python_classes>py test.py

The code executed as a module **from** some other program

The code executed as a module **from** some other program

Working with math Module:

- Python provides inbuilt module math.
- This module defines several functions which can be used for mathematical operations.
- The main important functions are

- 1) sqrt(x)
- 2) ceil(x)
- 3) floor(x)
- 4) fabs(x)
- 5) log(x)
- 6) sin(x)
- 7) tan(x)
- 8)

```
1) from math import *
2) print(sqrt(4))
3) print(ceil(10.1))
4) print(floor(10.1))
5) print(fabs(-10.6))
6) print(fabs(10.6))
```

Output

```
2.0
11
10
10.6
10.6
```

Note: We can find help for any module by using help() function

Eg:

```
import math
help(math)
```

Working with random Module:

- This module defines several functions to generate random numbers.
- We can use these functions while developing games, in cryptography and to generate random numbers on fly for authentication.

1) random() Function:

This function always generate some float value between 0 and 1 (not inclusive)
 $0 < x < 1$

```
1) from random import *  
2) for i in range(10):  
3)     print(random())
```

Output

```
0.4572685609302056  
0.6584325233197768  
0.15444034016553587  
0.18351427005232201  
0.1330257265904884  
0.9291139798071045  
0.6586741197891783  
0.8901649834019002  
0.25540891083913053  
0.7290504335962871
```

2) randint() Function:

To generate random integer between two given numbers(inclusive)

```
1) from random import *  
2) for i in range(10):  
3)     print(randint(1,100)) # generate random int value between 1 and 100(inclusive)
```

Output

```
51  
44  
39  
70  
49  
74  
52  
10  
40  
8
```

3) uniform() Function:

It returns random float values between 2 given numbers (not inclusive)

```
1) from random import *
2) for i in range(10):
3)     print(uniform(1,10))
```

Output

```
9.787695398230332
6.81102218793548
8.068672144377329
8.567976357239834
6.363511674803802
2.176137584071641
4.822867939432386
6.0801725149678445
7.508457735544763
1.9982221862917555
```

random() → in between 0 and 1 (not inclusive)

randint(x,y) → in between x and y (inclusive)

uniform(x,y) → in between x and y (not inclusive)

4) randrange ([start], stop, [step])

- Returns a random number from range
- start <= x < stop
- start argument is optional and default value is 0
- step argument is optional and default value is 1
- randrange(10) → generates a number from 0 to 9
- randrange(1,11) → generates a number from 1 to 10
- randrange(1,11,2) → generates a number from 1,3,5,7,9

```
1) from random import *
2) for i in range(10):
3)     print(randrange(10))
```

Output: 9

```
4
0
2
9
4
```

8
9
5
9

```
1) from random import *  
2) for i in range(10):  
3)     print(randrange(1,11))
```

Output: 2

2
8
10
3
5
9
1
6
3

```
1) from random import *  
2) for i in range(10):  
3)     print(randrange(1,11,2))
```

Output: 1

3
9
5
7
1
1
1
7
3

5) choice() Function:

- It won't return random number.
- It will return a random object from the given list or tuple.

```
1) from random import *  
2) list=["Sunny","Bunny","Chinny","Vinny","pinny"]  
3) for i in range(10):  
4)     print(choice(list))
```

Output

Bunny
pinny
Bunny
Sunny
Bunny
pinny
pinny
Vinny
Bunny
Sunny
